

TimeZone Quick Bot

This bot takes a predefined input denoting a source and target timezone and a datetime object, and converts between the locales. It does not parse the text intelligently, all errors are handled lazily.

With the info command, it tells some things about itself. For the help command, it shows the exact syntax that must be used.

On the proper command, it converts the timezones between the source and the target timezones. The timezones should be given as specified in the [tz database](#). The datetime object follows the syntax:

year:month:day(T as a delimiter)hour:minute:second.

Leading zeroes should be left off.
